ASSIGNMENT-8

NAME: Katakam Venkat

HT.NO: 2403A52053

BATCH: AIB03

Task-1

Write a test case to check if a function returns the square of a number. Then write the function with help from GitHub Copilot or Cursor AI.

Prompt:

1**2=1,2**2=4,3**2=9,4**2=16,5**2=25,6**2=36,7**2=49,8**2=64,9
2=81,102=100. according to the test case given to you, write a
function to generate square of a given number. input is given
dynamically

Code:

OP:

Observation:

The calculate_square function takes a number as input and returns its square using the ** operator. I have prompted to input a number dynamically. The program calculates the square of the input number and prints the result.

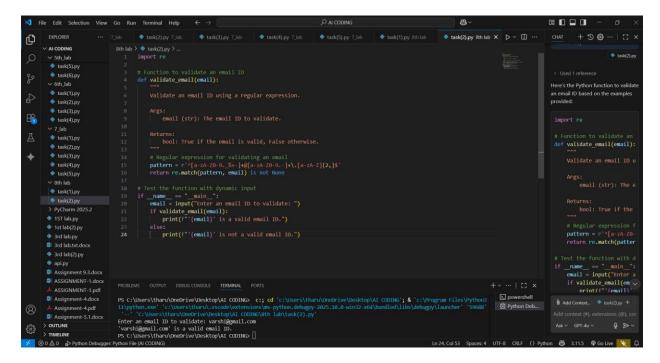

Task-2:

Create test cases to validate an email address (e.g., contains @ and .com).Use AI assistance to implement the validate_email() function

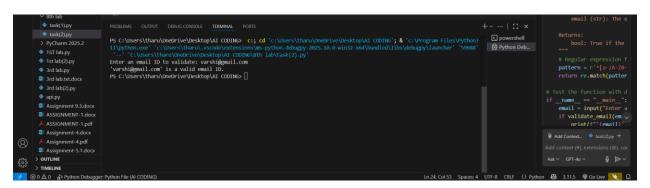

Prompt:

write a function which validates a email id. examples of a mail id is containt@gmail.com, madam@gmail.com, anyone@gmail.com. according to the test case/examples given generate code.

Code:

OP:

Observation:

Examples like containt@gmail.com, madam@gmail.com, and anyone@gmail.com are valid because, They contain alphanumeric characters before the @. They have a domain name after the @ (e.g., gmail.com). The domain name ends with a valid top-level domain (e.g., .com). Emails without an @ symbol or domain name are invalid. Emails with special characters in invalid positions (e.g., @example.com or name@.com) are invalid.

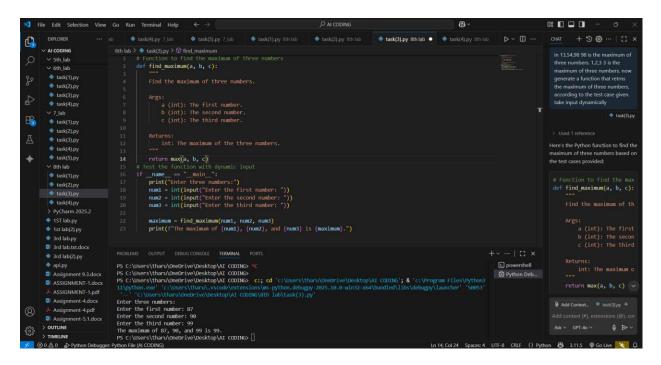

Task-3:

Write test cases for a function that returns the maximum of three numbers. Prompt Copilot/Cursor to write the logic based on tests

Prompt:

in 13,54,98 98 is the maximum of three numbers. 1,2,3 3 is the maximum of three numbers. now generate a function that returns the maximum of three numbers, according to the test case given. take input dynamically

Code:

OP:

```
# 3rd lab.py

#
```

Observation:

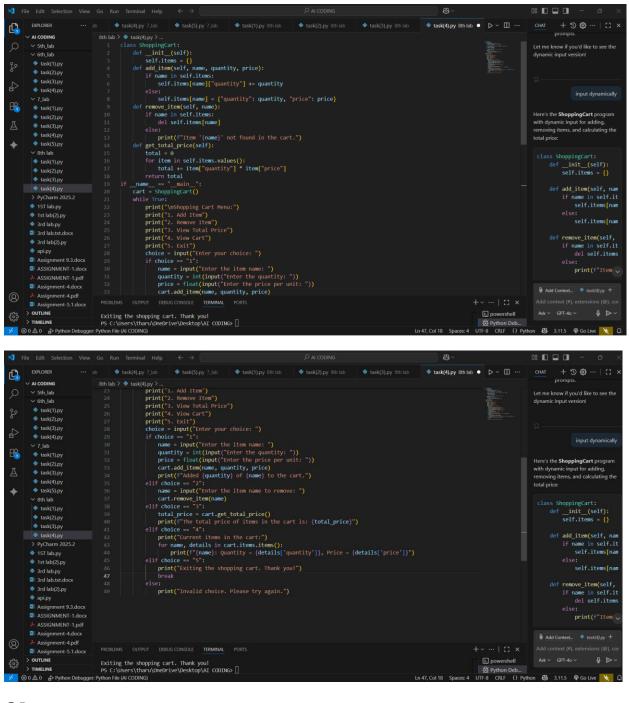

The find_maximum function takes three numbers as arguments and returns the maximum using Python's built-in max() function. I have prompted to input three numbers dynamically. The program calculates the maximum of the three numbers and prints the result.

Task-4:

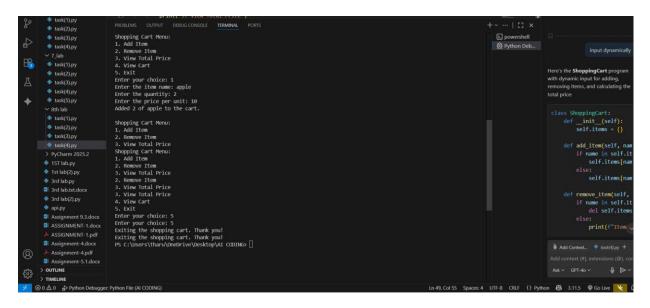

Use TDD to write a shopping cart class with methods to add, remove, and get total price. First write tests for each method, then generate code using AI.

Prompt: Now generate a Python class ShoppingCart that can add items, remove items, and calculate the total price according to the given test cases. Take input dynamically from the user. Input: Add Apple with quantity 2 and price $3.0 \rightarrow \text{Output}$: {"Apple": {"quantity": 2, "price": 3.0}}. Input: Remove Apple from the cart \rightarrow Output: {}. Input: Add Apple (quantity 2, price 3.0) and Banana (quantity 1, price 1.5) \rightarrow Output: Total price is 7.5.

Code:

OP:

Observation: The program uses input() to allow the user to interact with the shopping cart dynamically. Users can add items, remove items, view the total price, and see the cart's contents.

- Option 1: Add an item to the cart.
- Option 2: Remove an item from the cart.
- Option 3: Calculate and display the total price of items in the cart.
- Option 4: Display all items in the cart.
- Option 5: Exit the program.

If the user tries to remove an item that doesn't exist, the program displays an appropriate message

Task-5:

Write tests for a palindrome checker (e.g., is_palindrome("level") → True). Let Copilot suggest the function based on test case expectations.

Prompt:

write a function to check whether a word or a number is palindrome or not. Example: level, 121

Code:

```
File Edit Selection View Go Run Terminal Help C > PACCOONG

DOPLORER ... | task(Stypy Table | task(Stypy Table | task(Stypy Statub | task(Stypy St
```

OP:

Observation:

The input value is converted to a string using str(value) to handle both words and numbers. The function checks if the string is equal to its reverse using slicing (value[::-1]). I have prompted to enter a word or number dynamically. The program prints whether the input is a palindrome
